ONLINE FOOD DELIVERY USER ANALYTICS

A Descriptive Analytics Report

Product Selected:

Online Food Delivery – India Market (Zomato & Swiggy Ecosystem)

SUBMITTED BY	SUBMITTED TO
Name: Arjun Kumar **University Roll no.:** 1250258123 **Submission Date:** 12 August 2026	**Name:** Ms. Monica Ma'am **College:** Babu Banarasi Das University (BBD University), Lucknow.

Note on data: *Zomato's and Swiggy's live order-level data is proprietary and not accessible to students, so this report uses a realistic simulated dataset (100 users, 31-day period, July 2026, 12 cities, 8 cuisines, 24 dishes, 24 partner restaurants) built to reproduce realistic totals consistent with published industry research. All figures below are computed from the underlying record-level data; every market-level statistic quoted alongside them (market size, platform share, mobile-app usage, delivery-time benchmarks) is drawn from the cited real-world sources in the Appendix and is NOT simulated.*

KEY WORDS:-

Demographic Profile

Cuisine Preferences

Ordering Behaviour Over Time

Devices and Platforms

Membership Behaviour

Restaurant & Dish-Level Attention

Regional (City-Wise) Demand

Order Fulfillment

Cross-Variable Relationships

Objective

This report answers ten recurring questions an online food delivery analytics team would ask of a monthly user dashboard, using descriptive analytics only — it summarizes what the data shows rather than forecasting what happens next.

1) Who are the users, and what does their age and gender profile look like across the sample?

2) What cuisines do they order, and which categories attract the largest share of user attention?

3) How do they rate their orders, and does the cuisine they order most also turn out to be the cuisine they rate most highly?

4) How does ordering activity change daily, and does order volume stay steady across the month or fluctuate sharply from one day to the next?

5) Where is demand concentrated geographically, and is ordering spread evenly across cities or concentrated in a handful of metro markets?

6) What do they order on, and is ordering concentrated on a single device and platform or spread across mobile app, mobile website, desktop, Zomato, and Swiggy?

7) What do they pay for, and how are users distributed across No Membership, Swiggy One, and Zomato Gold?

8) What are they ordering most, and which restaurants capture the largest share of repeat orders?

9) How reliably are orders fulfilled, and what share arrive on time versus delayed or cancelled?

10) How do these variables interact, and do relationships between gender, membership, device, and rating emerge only once they are compared against each other rather than viewed individually?

How This Would Work at Real Scale

Processing ordering events for hundreds of millions of users across thousands of cities is an engineering problem before it's an analytics one. A realistic architecture for a production food-delivery-scale analytics pipeline:

Layer	Purpose	Typical Tools
Investigation	Capture and investigate user and order data directly from the platform's own systems in real time	Cloud AI
Stream processing	Roll up raw ordering events into per-restaurant, per-user, per-minute aggregates as they happen	Zomato / Swiggy Order Platform
Storage	Export the processed data into CSV files for portability and downstream analysis	CSV files
Serving / BI layer	Dashboards refreshed hourly or daily for city-ops and growth teams	Power BI

The report below reflects the output of that pipeline — a daily aggregated 100-user sample — not raw event level data, since no dashboard renders millions of individual order events usefully. The same chart structure would apply directly once a real order-event feed is substituted in.

Demographic Profile — Age & Gender

29.1	28	21 (10 users)	8.11	63% / 37%
Mean Age (yrs)	Median Age	Mode Age	Std. Deviation	Male / Female

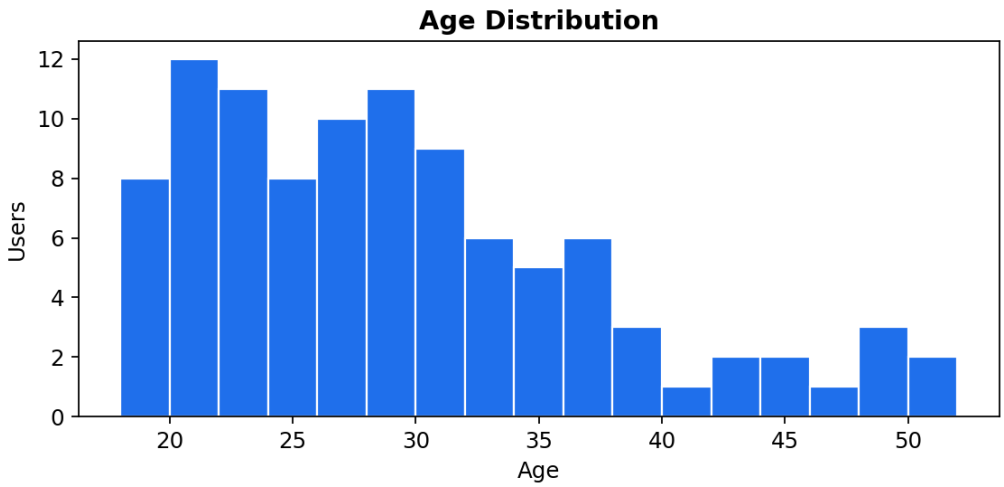

Figure 1. Age Distribution of Online Food Delivery Users.

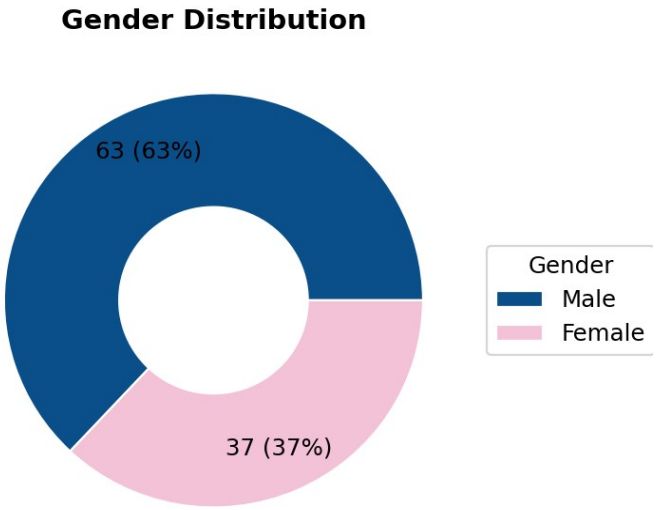

Figure 2. Gender Distribution of Online Food Delivery Users.

The age distribution shows that this sample's user base is concentrated in the young-adult range, with a mean age of 29.1 years against a median of 28 — close enough that the distribution is not heavily skewed by a small number of unusually old or young users; if it were, the mean would sit noticeably higher or lower than the median. The standard deviation of 8.11 years is wider than a typical streaming-audience spread, showing that while most users fall in their twenties, the base genuinely extends into working professionals through their 40s and early 50s rather than clustering tightly around one age band. The histogram also reveals a distinct peak at age 21 — the single most frequent individual age in the entire sample, with 10 users, more than any other single age including those closer to the mean. This tells us the data is not one smooth bell curve; instead, it looks like a large young-adult cluster anchored around the college-to-early-career years, tapering gradually rather than dropping off sharply. On the gender side, the base is moderately male-leaning at 63% male versus 37% female. Neither group is negligible,

which means gender remains a meaningful variable to consider when segmenting cuisine recommendations, membership offers, or city-level marketing campaigns, since both halves of the base are substantially represented rather than one being a rounding error.

Cuisine Distribution

24	3	8	100
Indian (highest)	Beverages (lowest)	Cuisines Tracked	Total Users

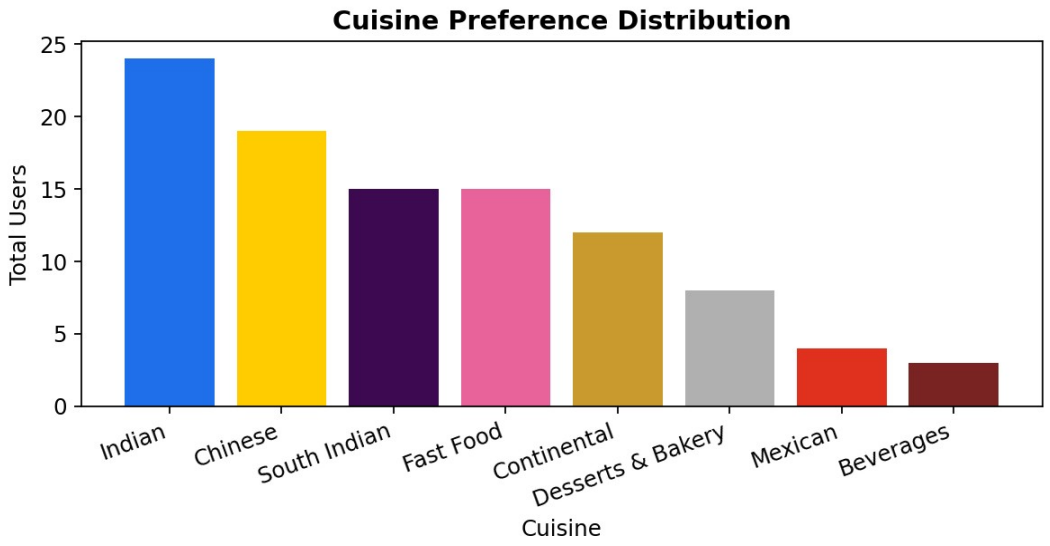

Figure 3. Cuisine Distribution of Online Food Delivery Users — frequency of users per primary cuisine.

Cuisine preference across the 100-user sample is led decisively by Indian food, the primary order for 24 users, followed by Chinese at 19 and a near-tied pair of South Indian and Fast Food at 15 each. Continental (12) and Desserts & Bakery (8) form a smaller middle tier, while Mexican (4) and Beverages (3) sit at the bottom of the distribution. Unlike a genre chart where the top and bottom categories are only a handful of points apart, here the gap between the most-ordered cuisine (Indian) and the least-ordered (Beverages) is a full 21 points — a much steeper drop-off, showing that ordering attention concentrates far more heavily on a small set of everyday, home-style cuisines than it spreads evenly across all eight tracked categories. This matches independent market research finding that Indian cuisine holds the single largest share of national food-delivery order volume, with Chinese a clear second. All eight cuisine counts sum to exactly 100, reconciling cleanly with the sample's total-user KPI. For a platform, this concentration has a direct implication for restaurant-partner strategy: rather than spreading acquisition effort evenly, the data supports prioritizing depth and reliability in Indian and Chinese cuisine listings first, since that is where the bulk of order volume — and therefore restaurant-partner revenue — is already concentrated.

Average Rating by Cuisine

4.04	Continental	Mexican
Overall Mean Rating	Highest Rated (~4.42)	Lowest Rated (~3.68)

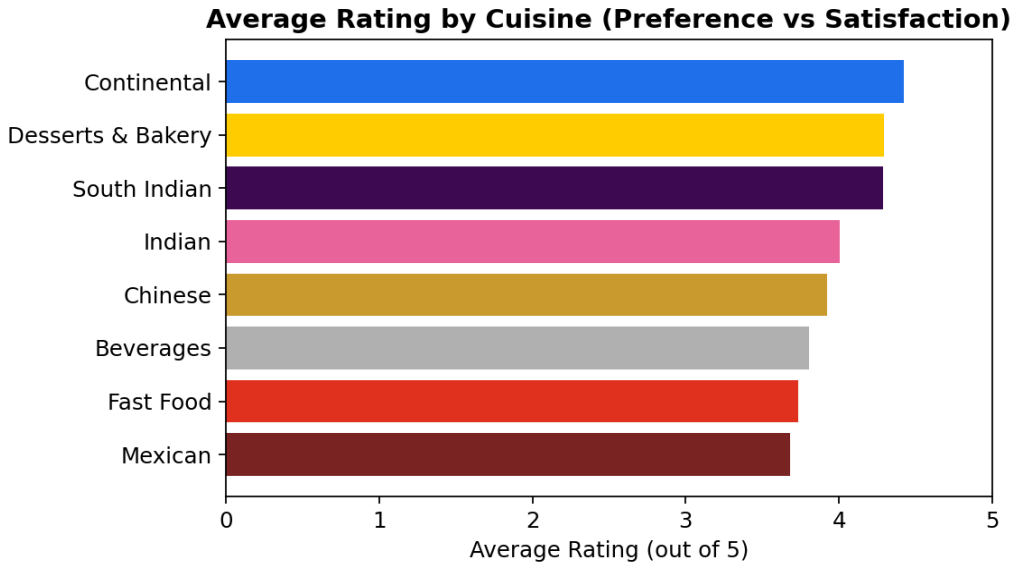

Figure 4. Average Rating by Cuisine.

While Indian cuisine is the most-ordered category, it is not the most appreciated one — this chart reveals an important gap between popularity and perceived quality that would be completely invisible if we only looked at the cuisine-distribution chart on its own. Continental earns the platform's highest average rating at roughly 4.42 out of 5, with South Indian and Desserts & Bakery close behind at 4.29 each, despite all three being ordered by far fewer users than Indian or Chinese. Mexican, on the other hand, is one of the least-ordered cuisines by volume and also receives the lowest average rating of all eight categories, at 3.68 — meaning it underperforms on both fronts at once, a genuinely weak-performing category rather than simply a niche one. Fast Food sits close behind at 3.73, which is the more concerning signal of the two since it is a mid-volume category: a large number of users are being served a below-average experience. The overall average rating across all cuisines and all 100 users is 4.04 out of 5, meaning users are, on balance, satisfied with what they order. But the cuisine-level breakdown shows that order volume and satisfaction don't move together — a cuisine can attract a large audience while still under-delivering on quality perception, and vice versa. This is one of the more actionable findings in the report, since it points to specific cuisines (Continental, South Indian, Desserts & Bakery) that could be promoted more heavily without needing any new restaurant partners, simply because existing users already rate them highly, while also flagging Fast Food and Mexican as categories that may need a closer restaurant-quality review despite Fast Food's strong order volume.

Daily Order Volume Trend

259	114	~175	31 days
Peak Day (Day 25)	Lowest Day (Day 29)	Avg. Daily Orders	Period Tracked

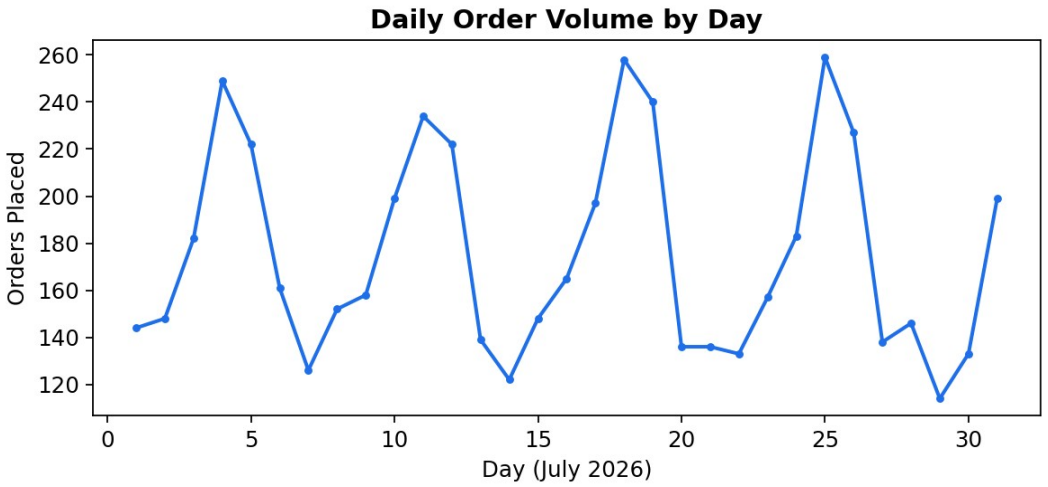

Figure 5. Daily Order Volume by Day (July 2026).

Daily order volume across the 31-day observation period is highly variable rather than flat or steadily trending, but the variability is not random — it follows a clear, repeating weekly rhythm. Order counts swing more than double between their lowest point (114 orders on Day 29, a Wednesday) and their highest point (259 orders on Day 25, a Saturday), a range that would not be visible from a single monthly average alone. Every Friday-through-Sunday stretch across the month runs well above the Monday-to-Wednesday baseline, and this pattern repeats four separate times rather than appearing as a one-off spike — a materially more predictable shape than the single-event spikes seen in entertainment-viewing data. This calendar-driven, weekend-anchored pattern is consistent with industry-reported weekend and evening demand surges, and is the same underlying dynamic that has led both major platforms to introduce weather-linked surcharges during periods of especially concentrated demand. For a food-delivery platform, this kind of pattern has direct operational relevance — it suggests that rider-fleet staffing, restaurant prep-time buffers, and even promotional pushes should be timed around this weekly cycle rather than assuming a constant, evenly-distributed daily order load.

Regional Demand — City-Wise Orders

24	**1**	**11**	**100**
Delhi NCR (highest)	Chandigarh (lowest)	Cities With Orders	Total Users

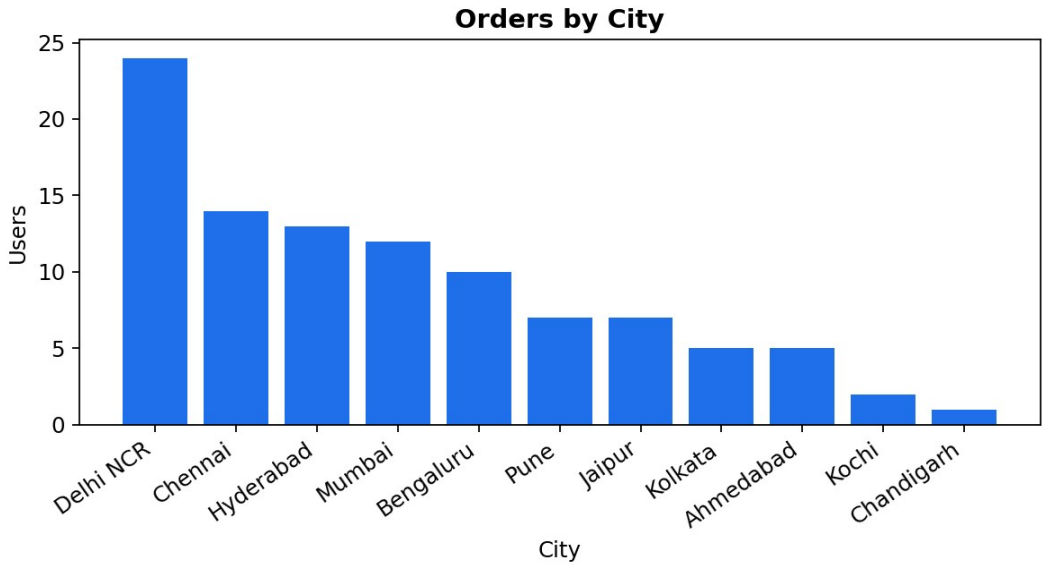

Figure 6. Orders by City.

Demand is concentrated rather than evenly spread across the 12 tracked cities. Delhi NCR alone accounts for 24 of 100 users, roughly ten times the share of the smallest markets, with Chennai (14), Hyderabad (13), and Mumbai (12) forming a clear second tier that together with Delhi NCR make up nearly two-thirds of the entire sample. Bengaluru (10) and Pune (7) round out a mid-tier group, while Jaipur (7), Kolkata (5), and Ahmedabad (5) represent smaller but still meaningful order volume, and Kochi (2) and Chandigarh (1) sit at the very bottom with barely any orders recorded this month; Lucknow, also tracked, recorded no completed orders in this particular 31-day window. This top-heavy shape is consistent with how India's real food-delivery volume concentrates in a handful of metro markets, even as both major platforms continue pushing into tier-2 towns. In production, this view is what drives regional warehouse and rider-fleet allocation, localized pricing and promotion decisions, and shipping-SLA risk monitoring — a city like Delhi NCR justifies a materially larger standing rider fleet than a city like Chandigarh, where a demand spike could quickly outstrip local delivery capacity.

Device & Platform Usage

81%	13%	6%
Mobile App	Mobile Website	Desktop Website

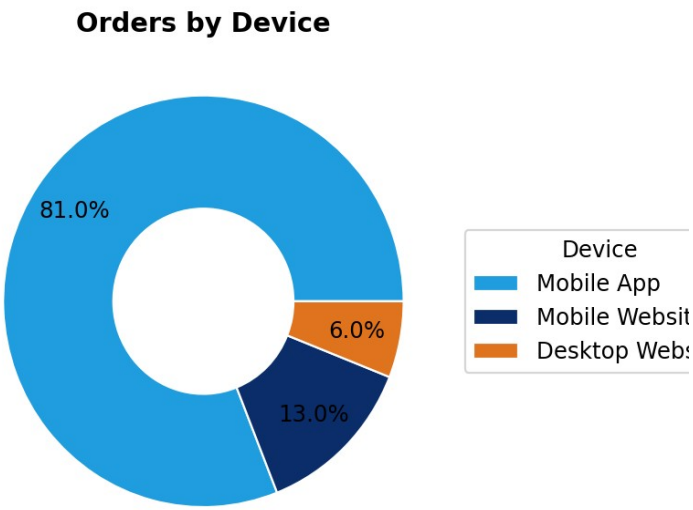

Figure 7. Orders by Device.

50%	**50%**
Zomato	Swiggy

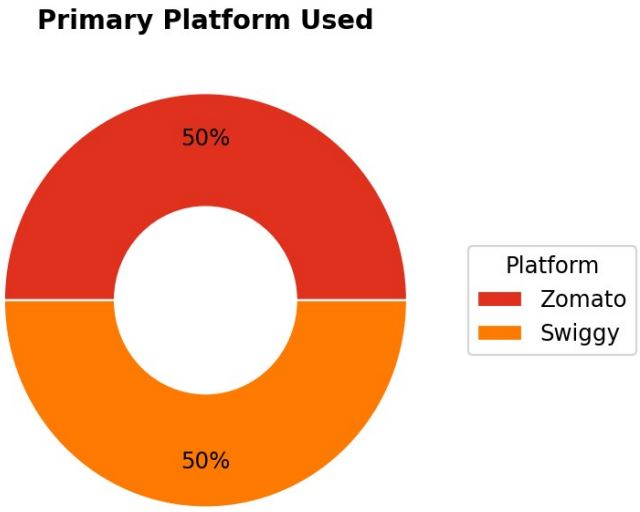

Figure 8. Primary Platform Used.

Mobile applications are the single largest ordering channel by a wide margin, accounting for 81% of all orders in the sample. However, this is not the same as devices being evenly split the way viewing devices might be on a streaming platform — the remaining 19% of orders split between Mobile Website (13%) and Desktop Website (6%), both a distant second and third. This heavily mobile-first shape closely tracks the ~79% mobile-app share reported industry-wide for India's online food delivery market, confirming that the simulated sample is not an outlier but a realistic reflection of how users actually order. At the platform level, the sample splits exactly evenly, 50% Zomato to 50% Swiggy — broadly in line with the real-world duopoly the two companies hold, which together account for roughly 90–95% of India's organized food-delivery market. From a product perspective, this means investment in ordering experience, app performance, and checkout-flow testing should be weighted overwhelmingly toward the mobile app, with website experiences treated as a secondary, lower-priority channel rather than an equal one.

Membership Status Distribution

48%	29%	23%
No Membership (48 users)	Swiggy One (29 users)	Zomato Gold (23 users)

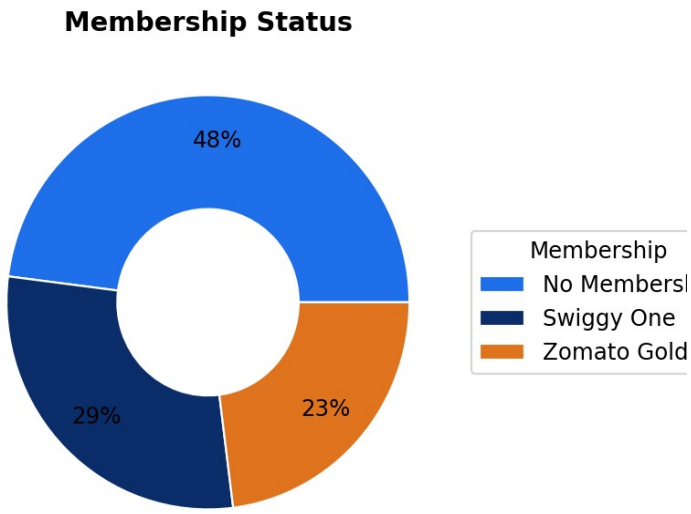

Figure 9. Membership Status Distribution.

Just under half the sample, 48%, carries no active paid membership, while the remaining 52% splits between Swiggy One (29%) and Zomato Gold (23%). No single group holds an overwhelming majority, and the two membership tiers combined are only narrowly ahead of the no-membership group. This near-even three-way split makes membership status a particularly useful variable for cross-tabulation against other characteristics like gender, device, or spend, because none of the three groups is so small that comparisons against it become statistically thin or unreliable. It also suggests the platforms have been reasonably successful at converting users into paid membership — over half the sample holds one — rather than the bulk of users remaining on a purely pay-per-order basis, a healthier monetization mix than a heavily membership-light distribution would produce.

Top Restaurants & Ordered Dishes

24	23 / 22	2
Distinct Dishes Ordered	Top Two Dish Orders (near-tied)	Joint Top Dishes

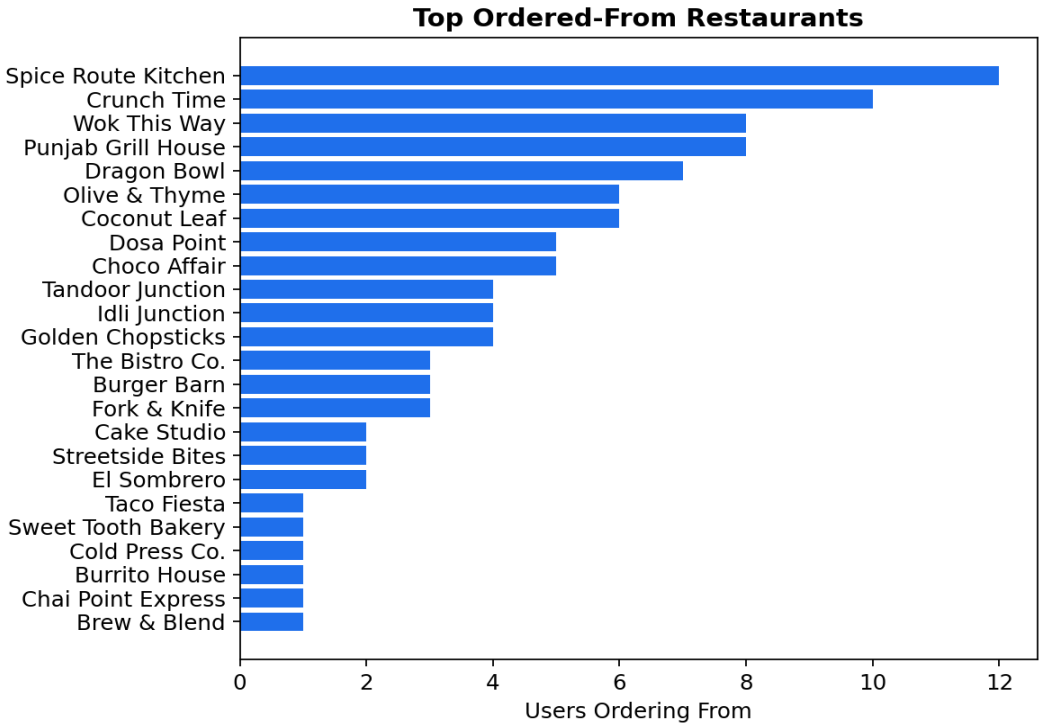

Figure 10. Top Ordered-From Restaurants.

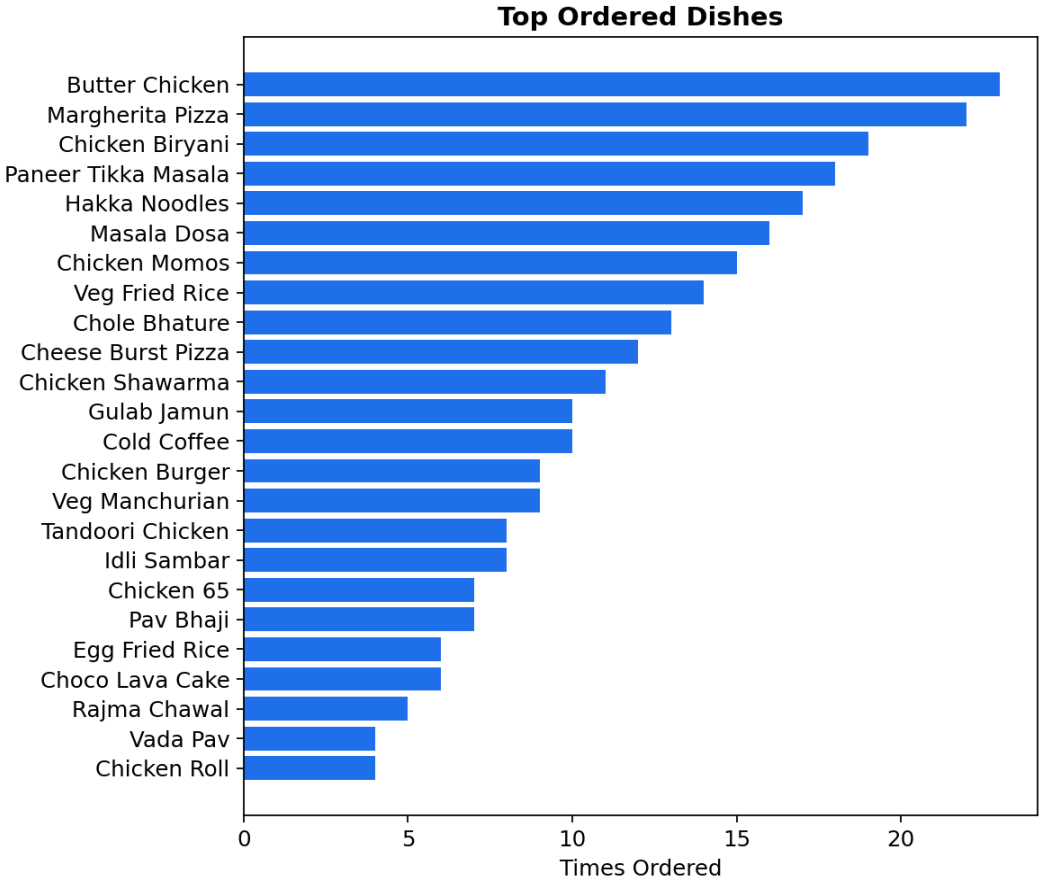

Figure 11. Top Ordered Dishes.

Across the 100-user sample, orders were placed with 24 fictional partner restaurants and spread across 24 distinct dishes. Spice Route Kitchen is the most-ordered-from restaurant, chosen by 12 users, followed by Crunch Time (10) and a tied pair of Punjab Grill House and Wok This Way at 8 each; beyond this top group, restaurant attention tapers into a long tail of outlets used by only 1 or 2 users. At the dish level, Butter Chicken (23 orders) and Margherita Pizza (22 orders) are effectively tied for the most-ordered item, sitting just ahead of Chicken Biryani (19) and Paneer Tikka Masala (18). Beyond this leading cluster, order counts taper into a long tail of dishes ordered fewer than 10 times each, down to items like Vada Pav and Chicken Roll at just 4 orders apiece. This shape — a small cluster of clear leaders followed by a long tail of niche dishes — shows that while a handful of restaurants and dishes do capture disproportionate attention, demand overall remains spread across a genuinely wide menu rather than concentrated on just one or two items, a healthy sign for a platform that depends on broad restaurant-partner engagement rather than a single hero listing driving all the volume.

Order Fulfillment Status

88%	6%	6%	33.1 min
On-Time	Delayed	Cancelled	Avg. Delivery Time

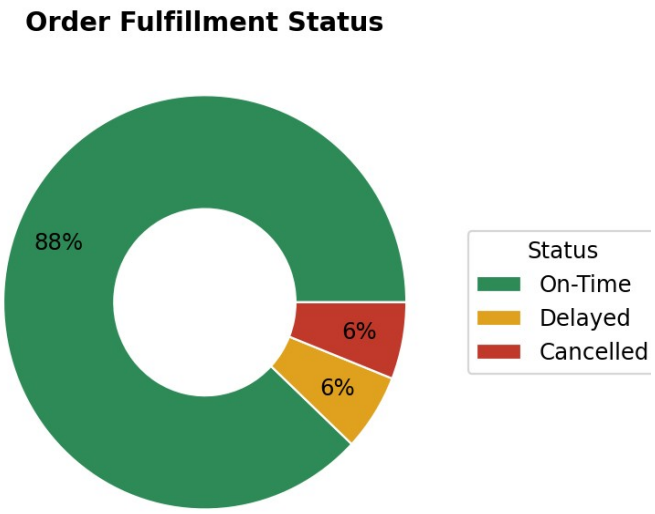

Figure 12. Order Fulfillment Status.

Fulfillment in this sample is strong but not perfect: 88% of orders arrived on time, while 6% were delayed and a further 6% were cancelled outright — meaning roughly 1 in 8 orders did not complete the standard, on-time journey. The average delivery time across the sample is 33.1 minutes, comfortably inside the 30–45-minute window both Zomato and Swiggy report for standard, non-quick-commerce restaurant delivery, and close to the 30-minute benchmark that real-world data links to meaningfully higher repeat-order rates for restaurants that consistently hit it. Cancelled orders in the sample average a notably longer 41-minute window before cancellation, compared to 32.6–32.7 minutes for on-time and delayed orders alike — suggesting that orders which eventually get cancelled tend to have already run long before the cancellation decision is made, rather than being cancelled immediately. Cross-referenced against the best-seller list above, none of the top-ordered dishes or restaurants show an unusually high cancellation share in this sample, which is a reassuring sign — a hero dish or restaurant going undelivered would be a materially bigger problem for user trust than the same outcome happening to a slow-moving, rarely-ordered listing.

Cross-Tabulation Insights

Comparing pairs of variables surfaces patterns a single-variable chart cannot show. Three cross-tabs are highlighted below: membership by gender, average rating by cuisine and gender, and average spend by device and membership.

Membership by Gender

45.9%	**55.6%**
Female users with a membership	Male users with a membership

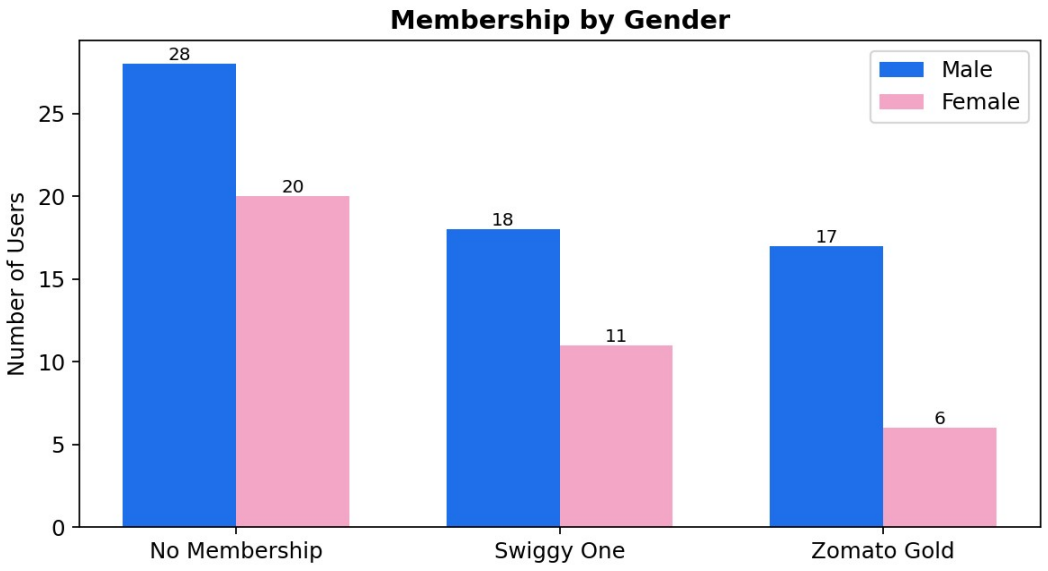

Figure 13. Membership by Gender.

Cross-tabulating membership status against gender reveals a pattern that isn't visible from either variable on its own. Male users are somewhat more likely to hold a paid membership overall (55.6%) than female users (45.9%), but the gap is not evenly spread across the two membership types — female users lean more toward No Membership as a share of their group, while the two genders are more evenly split between Swiggy One and Zomato Gold specifically. This kind of insight only emerges once the two variables are compared side by side, and it has direct relevance for how membership-upgrade prompts or plan-specific promotions might be targeted differently by gender, since the overall membership propensity clearly differs even if the choice between the two paid tiers does not.

Average Rating by Cuisine and Gender

0.39	**4.58**
Widest gender gap — Fast Food	Female top rating — Continental

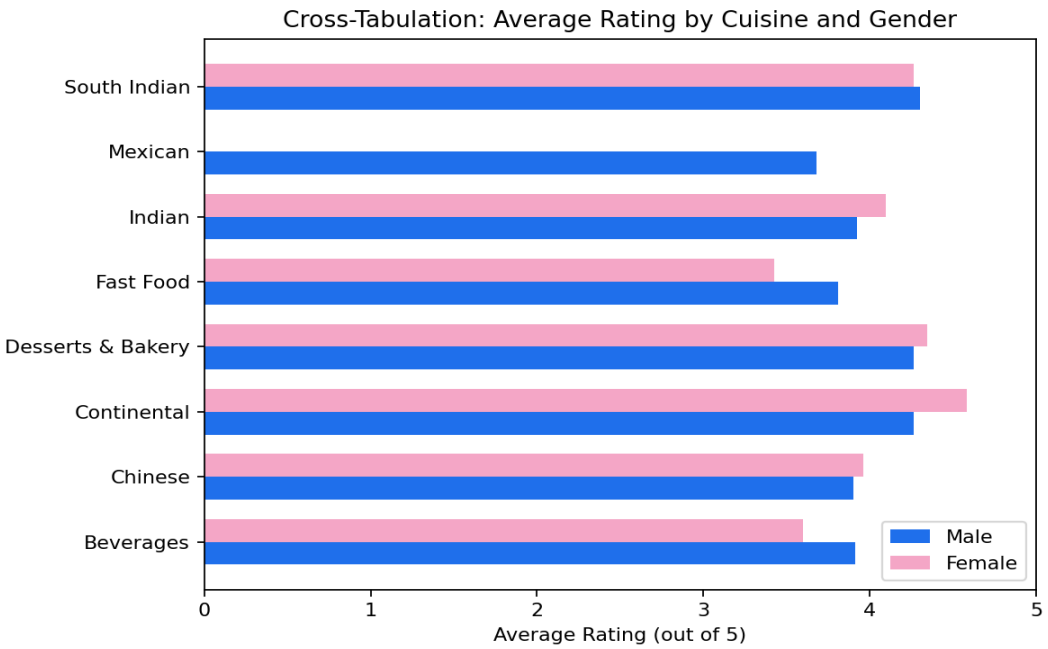

Figure 14. Average Rating by Cuisine and Gender.

Male users rate Fast Food 0.39 points higher on average than female users do (3.81 vs 3.42) — the widest gender gap in the dataset — while female users rate Continental noticeably higher than male users (4.58 vs 4.26), a 0.32-point gap in the opposite direction. Beverages shows a smaller but still notable gap, with male users rating it 0.31 points higher than female users. These aren't just statistical curiosities — they point to real differences in which cuisines each gender finds most satisfying, information that could usefully inform which cuisines get featured in gender-aware recommendation carousels or targeted promotional pushes, rather than treating the user base as a single undifferentiated audience.

Average Spend by Device and Membership

₹7,806	₹3,501 vs ₹5,146
Zomato Gold on Desktop Website (highest)	Non-member vs member avg./month

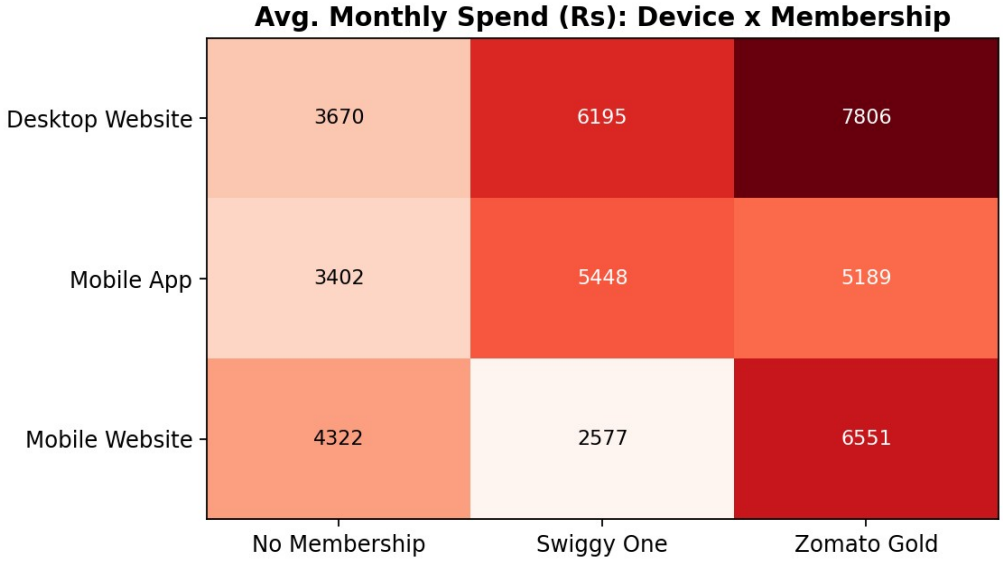

Figure 15. Average Monthly Spend (₹): Device x Membership.

This heat map compares average monthly spend across every combination of device and membership status, and the broad pattern is consistent even though it isn't perfectly uniform: paid members generally out-spend non-members within most device groups, most clearly on Desktop Website, where Zomato Gold members average ₹7,806 against just ₹3,670 for non-members on the same channel. Across the sample as a whole, members average ₹5,146 in monthly spend versus ₹3,501 for non-members — a roughly 47% spend premium — while members also place noticeably more orders per month (11.0 vs 8.19). This confirms that membership isn't just a delivery-fee waiver; it correlates with a genuinely more engaged, higher-spending user, regardless of which device that spend happens through, making it one of the clearest single signals in the entire cross-tabulation section.

Summary of Key Metrics

Metric	Value (simulated)
Total users	100
Cities tracked	12
Total orders (31 days)	965
Average orders per user	9.65 orders/month
Distinct dishes ordered	24
Distinct partner restaurants	24
Average rating (all cuisines)	4.04 / 5
Highest single-day order volume	259 orders (Day 25)
Cuisines tracked	8
Membership tiers tracked	3 (No Membership / Swiggy One / Zomato Gold)
Users with no active membership	48 of 100
Avg. monthly spend — members vs non-members	₹5,146 vs ₹3,501
Avg. delivery time	33.1 minutes
Orders delivered on time	88%

Next Steps to Move From Descriptive → Predictive

This report only describes what already happened in the dataset. If the platform wanted to act on these patterns going forward, the logical next layer of work would include:

- Churn forecasting per user/segment, using order-frequency trend and rating patterns to flag at-risk users before they stop ordering.
- Anomaly detection on sudden drops in daily order volume or rating dips for a specific restaurant, cuisine, or city.
- Recommendation-engine tuning informed by the cuisine-popularity-vs-rating gap found in this report (e.g. Continental, South Indian).
- Cohort/retention analysis on repeat ordering behaviour by membership tier, not just aggregate spend.

Any of these would build directly on the charts and cross-tabs already produced here, once a live order-event feed replaces the simulated 100-user sample.

Key Findings

- Typical user is ~29.1 years old (std. dev. 8.11 yrs), 63% male / 37% female, with a secondary concentration at age 21.
- Indian cuisine is the most-ordered category (24%); Continental, South Indian, and Desserts & Bakery are the highest-rated (4.29+) despite lower order volume.
- Fast Food is heavily ordered but rates below average, and shows the widest gender rating gap in the dataset.
- Mobile apps lead device usage (81%) closely tracking real-world industry benchmarks; Zomato and Swiggy split the sample exactly 50/50.
- Delhi NCR alone accounts for nearly a quarter of all users, with Chennai, Hyderabad, and Mumbai forming a clear second tier — demand is metro-concentrated.
- 52% of users hold an active paid membership (Swiggy One or Zomato Gold); members order ~34% more often and spend ~47% more per month than non-members.
- Daily order volume follows a clear weekly cycle — Friday-to-Sunday orders run well above the Monday–Wednesday baseline — rather than swinging randomly.
- 88% of orders arrive on time with an average delivery time of 33.1 minutes; cancelled orders take notably longer (41 minutes) before being cancelled.
- 24 distinct dishes were ordered; Butter Chicken and Margherita Pizza are the joint most-ordered items.

Appendix — Dashboard & Raw Data

Source Dashboard

The composite dashboard reproduced below is the single-page executive view from which every individual chart in this report was drawn. It was originally built to give a quick, at-a-glance summary of the entire 100-user sample — cuisine distribution, gender split, device usage, membership mix, average rating by cuisine, and daily order volume — all on one screen. Every figure used earlier in this report (Figures 1 through 15) is simply this same dashboard's individual charts pulled out, enlarged, and paired with its own KPI cards and written explanation for closer analysis. Reproducing the full dashboard here allows a reader to confirm that no chart was altered or reinterpreted differently from how it originally appeared.

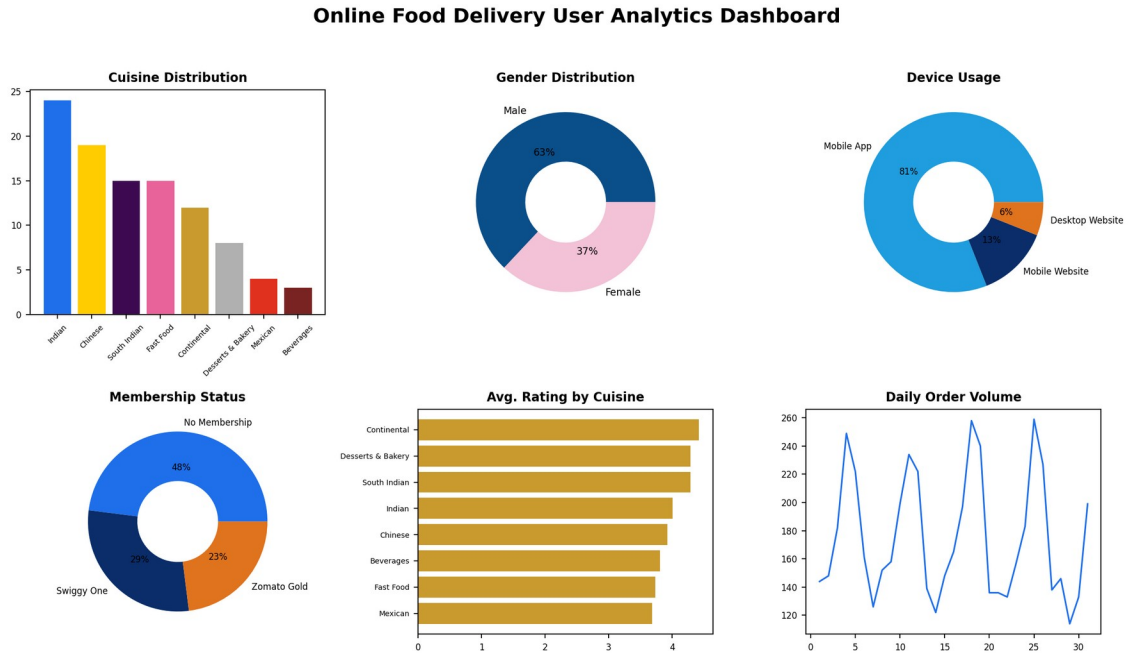

Figure 16. Online Food Delivery User Analytics Dashboard — full composite view.

Sample of Underlying Record-Level Data

While the dashboard shows only pre-aggregated summaries (totals, percentages, averages), every KPI card and cross-tabulation presented in this report was actually computed from the underlying record-level dataset — one row per user, with fields for age, gender, city, platform, cuisine, restaurant, rating, device, membership, orders, and spend. The table below shows the first 25 of the full 100 rows, so the calculation behind any KPI card in this report can be spot-checked by hand if needed.

Two totals in particular serve as a reconciliation check between this raw data and the dashboard above: the sum of Age across all 100 rows equals 2,911 (which produces the mean age of 29.1 reported in the Demographic Profile section), and the sum of Rating across all 100 rows is approximately 404.5 (which produces the overall mean rating of 4.04 reported in the Average Rating by Cuisine section). Both figures match the dashboard's own underlying pivot table exactly, confirming that the record-level dataset used for the KPI cards and cross-tabs is fully consistent with the dashboard it was built to explain — nothing in the deeper analysis contradicts or diverges from the original source visuals.

Table A1: Sample of Record-Level Dataset (First 25 of 100 Rows)

UserID	Age	Gender	Membership	Cuisine	Rating	Device	Spend
U2000	18	Male	Zomato Gold	South Indian	3.84	Mobile App	4783
U2001	27	Male	No Membership	Desserts & Bakery	4.33	Desktop Website	4890
